Lecture 1.2

Evolutionary Models

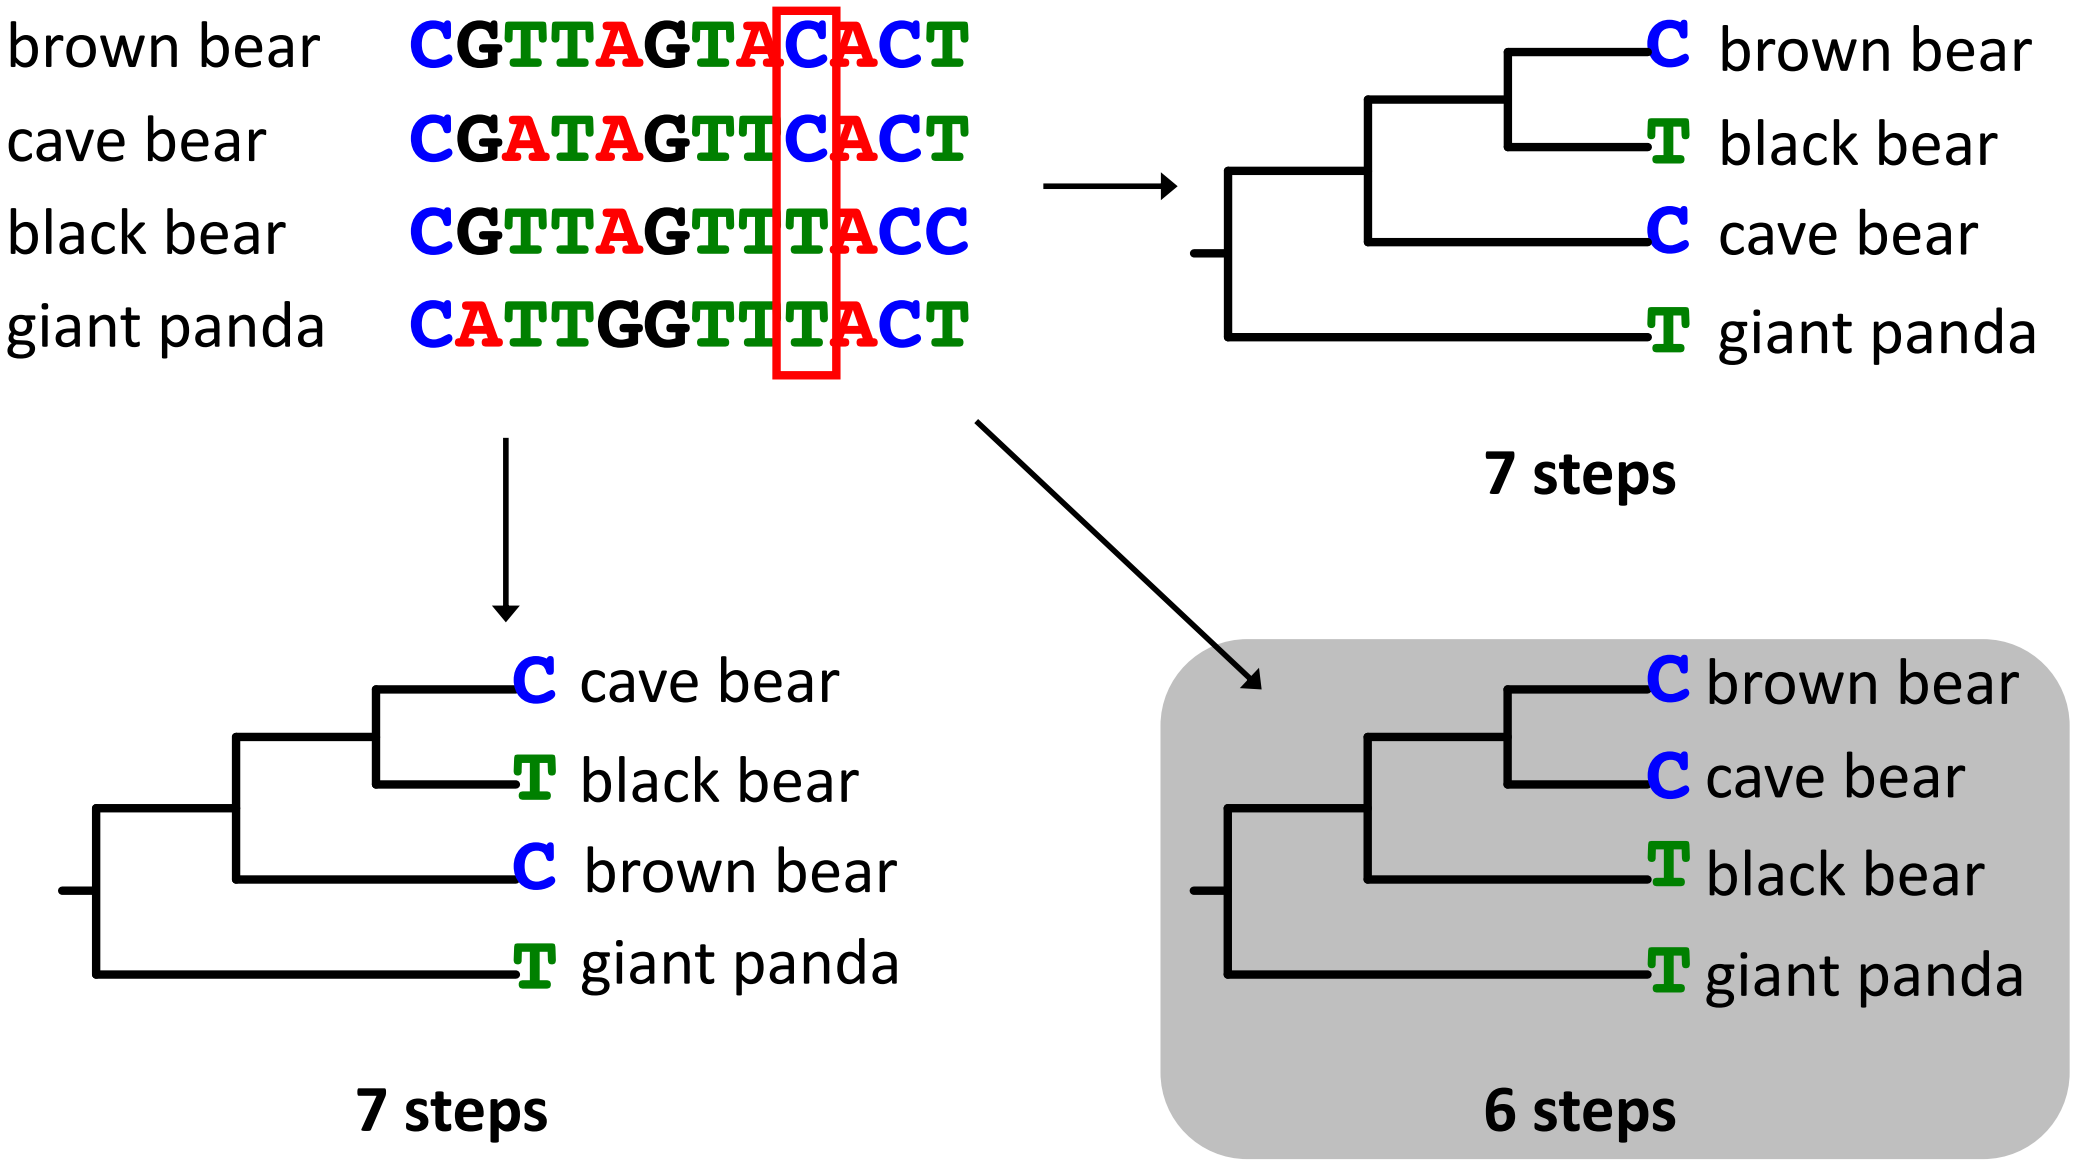
Popular phylogenetic methods

1. Maximum parsimony
2. Distance-based methods
3. Maximum likelihood
4. Bayesian inference

Model-based methods

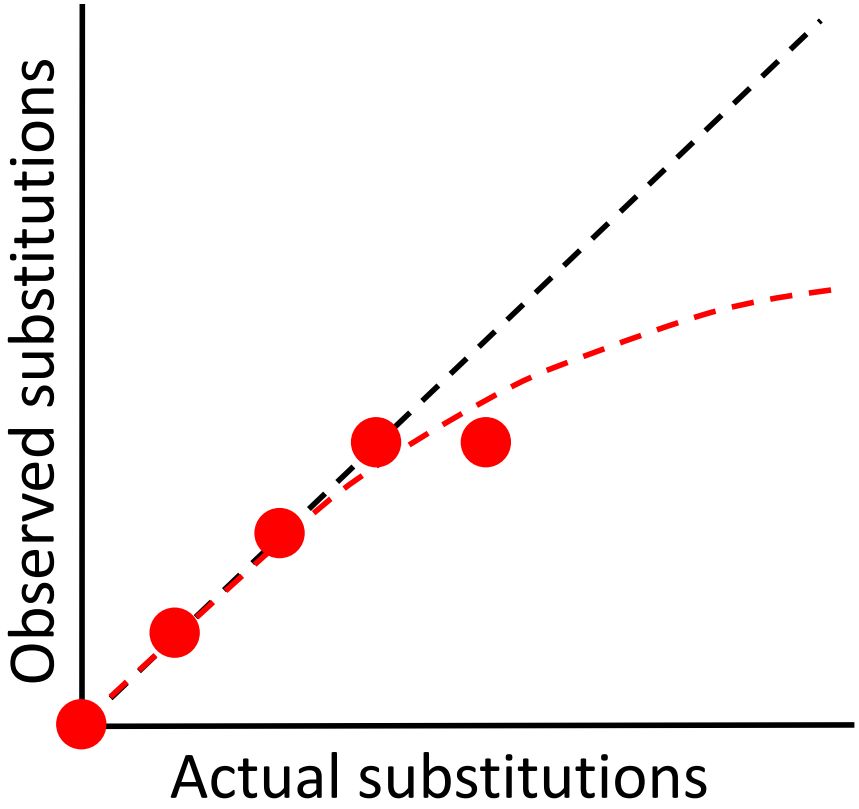
Maximum Parsimony

Maximum parsimony



Maximum parsimony

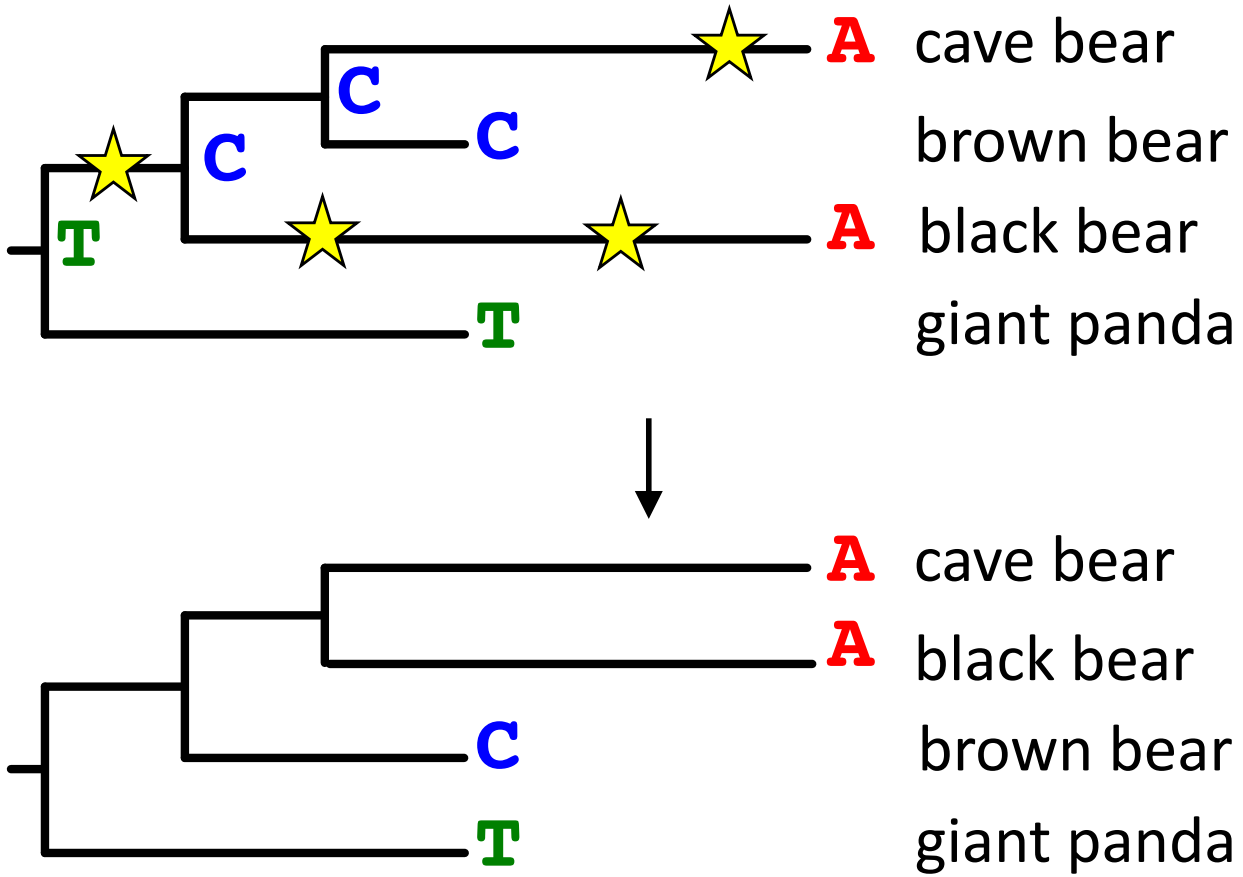
- Identifies the tree topology that can explain the sequence data, using the smallest number of inferred substitution events
- Commonly used for morphological data
- Now *rarely used* for analysing genetic data
  - Cannot estimate evolutionary rates or timescales
  - Effects of multiple substitutions



A	A	A	A	A
A	T	T	T	T
C	C	G	G	G
A	A	A	A	A
T	T	T	T	T
T	T	T	T	T
A	A	A	A	A
G	G	G	G	G
T	T	T	A	C

- Maximum parsimony does not correct for multiple substitutions at the same site
- This leads to a problem known as **long-branch attraction**
  - Long branch = many substitutions
  - Similarities arise by chance
  - Long branches cluster together

Long-branch attraction

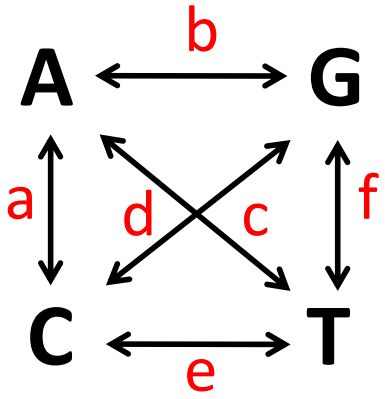


We can correct for multiple hits using substitution models

Substitution Models

Nucleotide substitution models

Rate Matrix



Base Frequencies

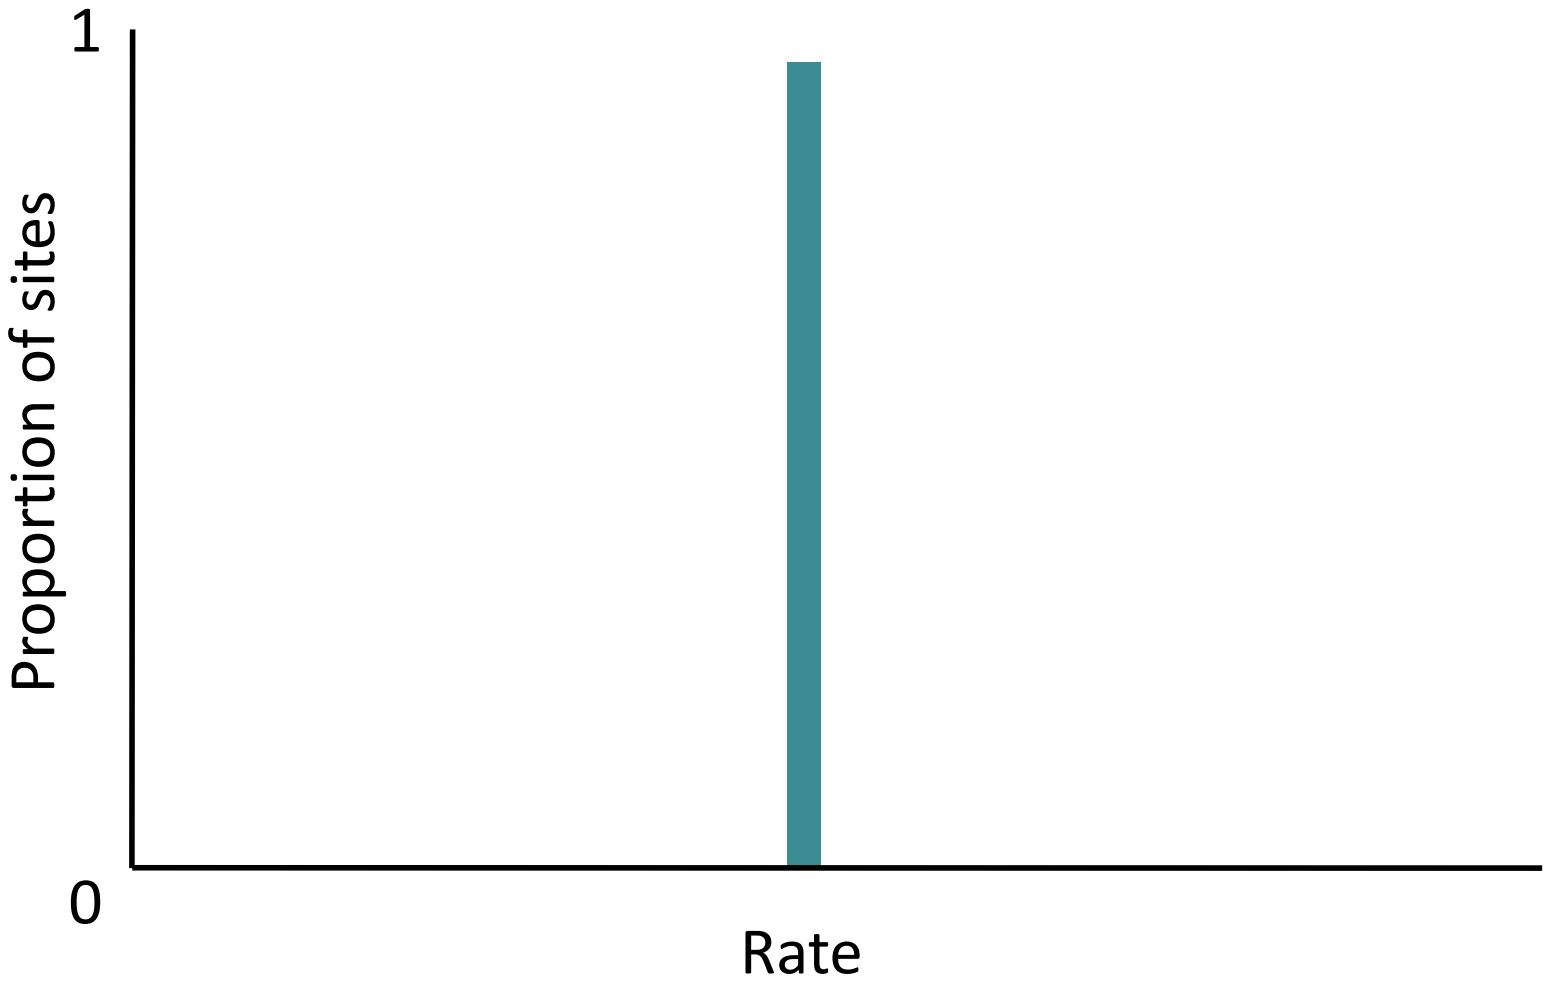
$\pi_A + \pi_C + \pi_G + \pi_T = 1$

JC	HKY	GTR
a=b=c=d=e=f	a=c=d=f, b=e	a, b, c, d, e, f
$\pi_A=\pi_C=\pi_G=\pi_T$	$\pi_A, \pi_C, \pi_G, \pi_T$	$\pi_A, \pi_C, \pi_G, \pi_T$

Rate variation across sites

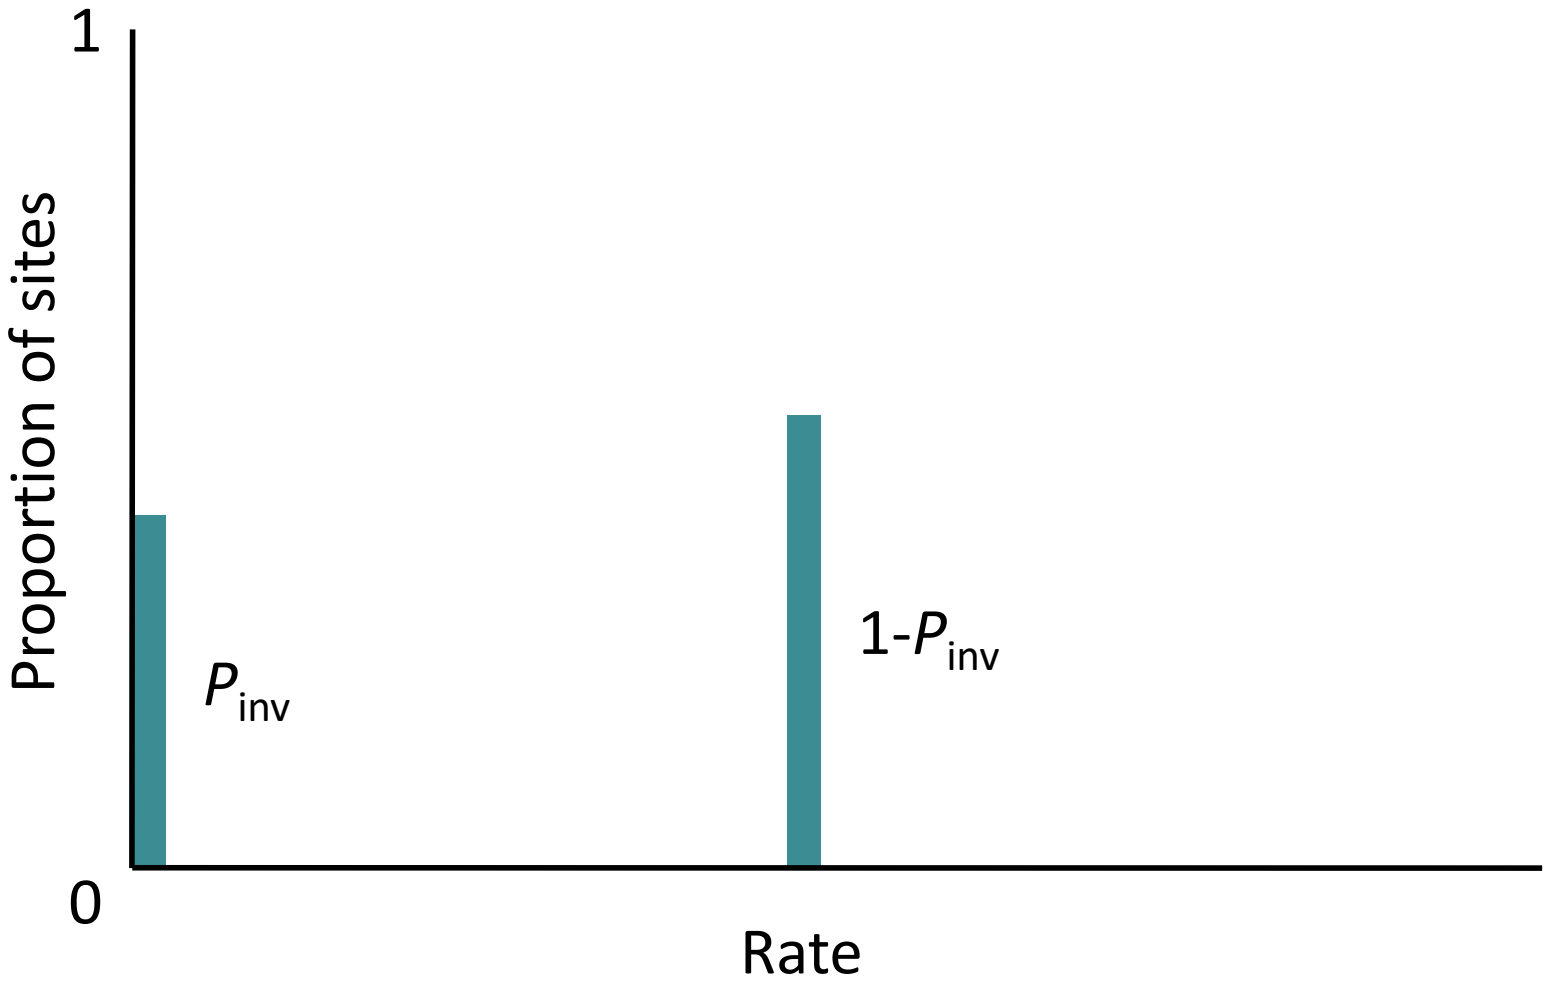
Rate variation across sites

- Equal rates among sites



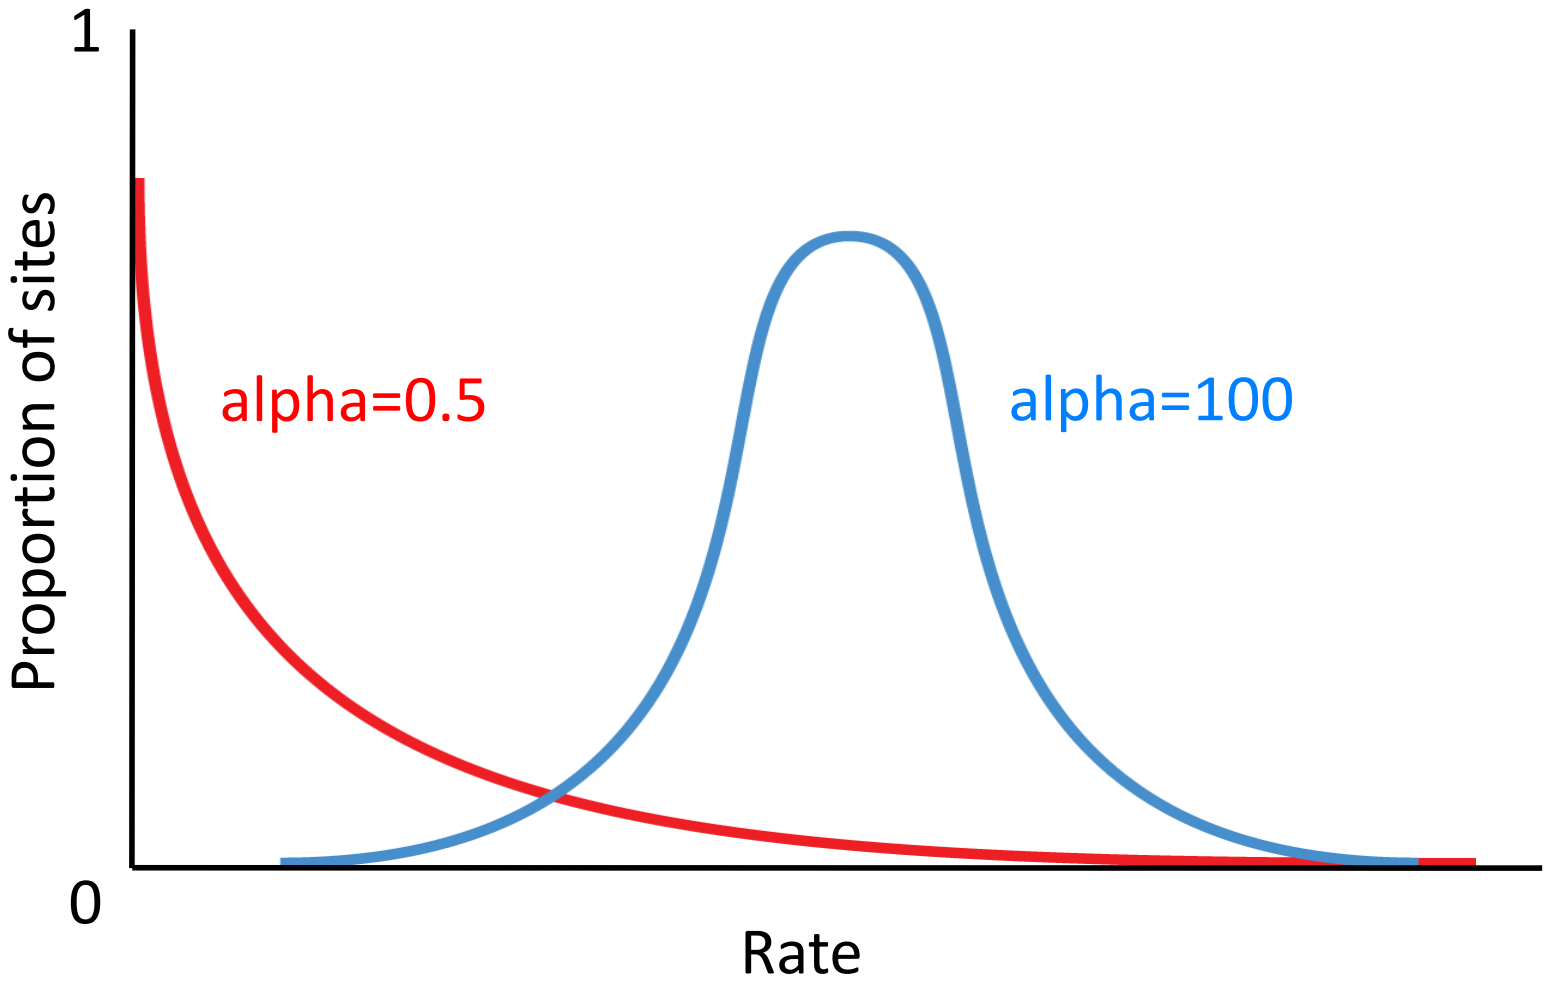
Rate variation across sites

- Proportion of invariable sites (**+I** models)



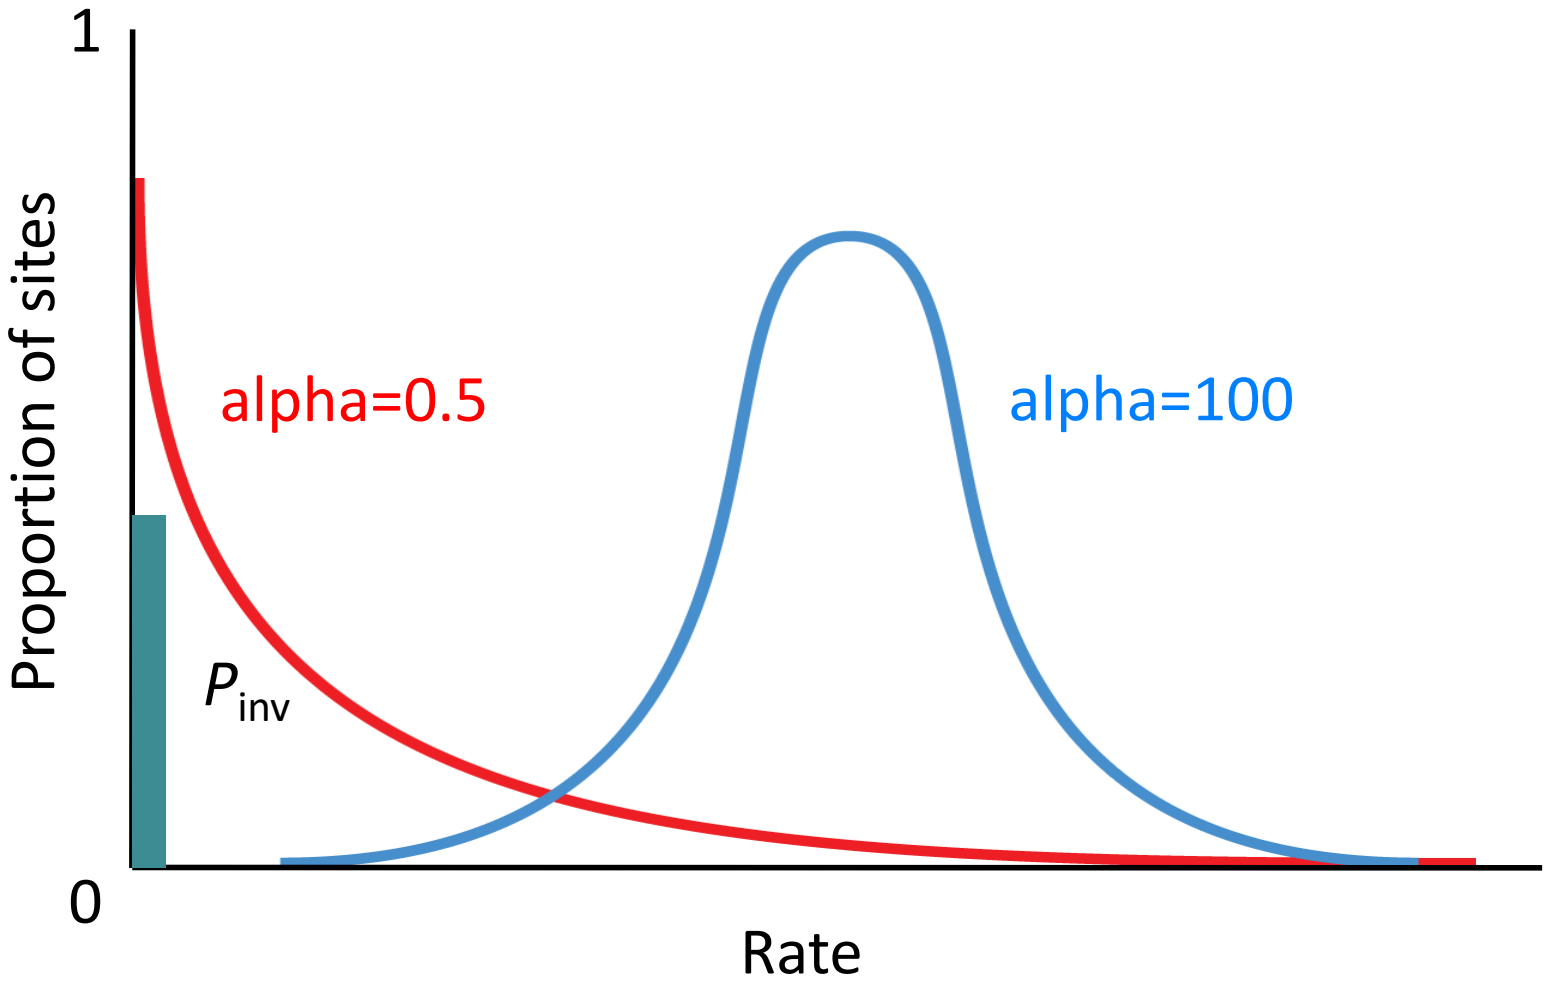
Rate variation across sites

- Gamma-distributed rate variation across sites (**+G** models)



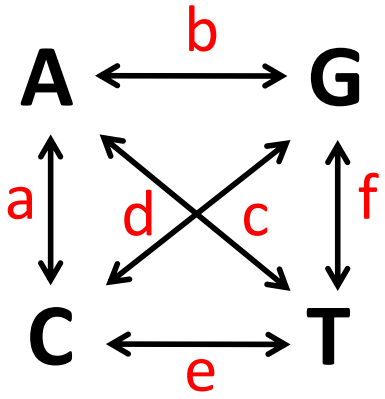
Rate variation among sites

- Gamma-distributed rate variation across sites and a proportion of invariable sites (**+G+I** models)



Nucleotide substitution models

Rate Matrix



Base Frequencies

$\pi_A + \pi_C + \pi_G + \pi_T = 1$

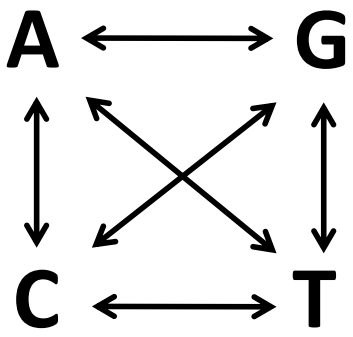
Site Rates

+ I + G

JC	**HKY**	**GTR**	**GTR+I+G**
a=b=c=d=e=f	a=c=d=f, b=e	a, b, c, d, e, f	a, b, c, d, e, f
$\pi_A=\pi_C=\pi_G=\pi_T$	$\pi_A, \pi_C, \pi_G, \pi_T$	$\pi_A, \pi_C, \pi_G, \pi_T$	$\pi_A, \pi_C, \pi_G, \pi_T$
			I, G

Nucleotide substitution models

Rate Matrix



Base Frequencies

$\pi_A + \pi_C + \pi_G + \pi_T = 1$

Site Rates

+ I + G

#Models

203 x 15 x 4 = 12,180

In phylogenetics, we typically consider a small subset of these

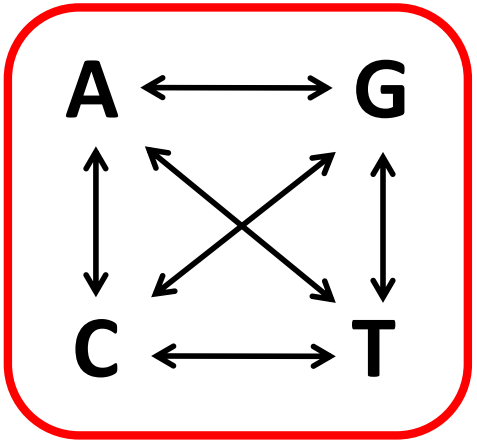
Proportion of invariable sites

- Often overestimated in analyses of intraspecific data
- Unable to distinguish between:
  - Sites that are **invariable** and unable to change
  - Sites that are **constant** and by chance have not mutated
- Not biologically meaningful
- Slowly evolving sites taken into account by **+G**

Use +G models to account for rate variation across sites

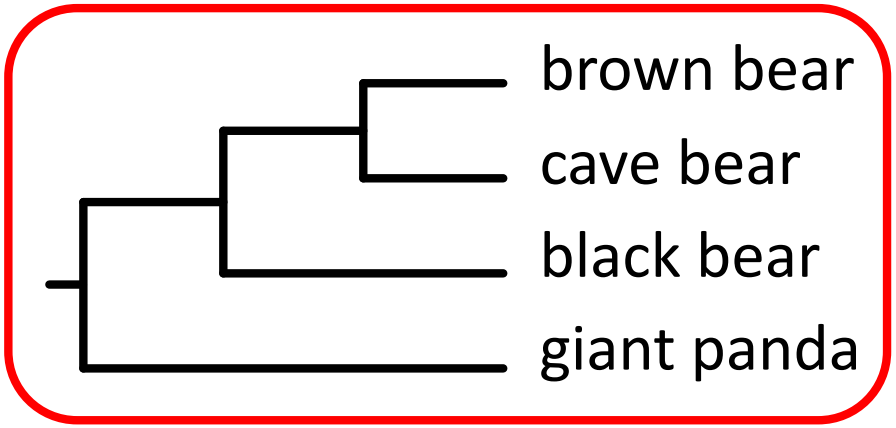
Fundamental assumptions

Reversible



Stationary

$$\pi_A + \pi_C + \pi_G + \pi_T = 1$$



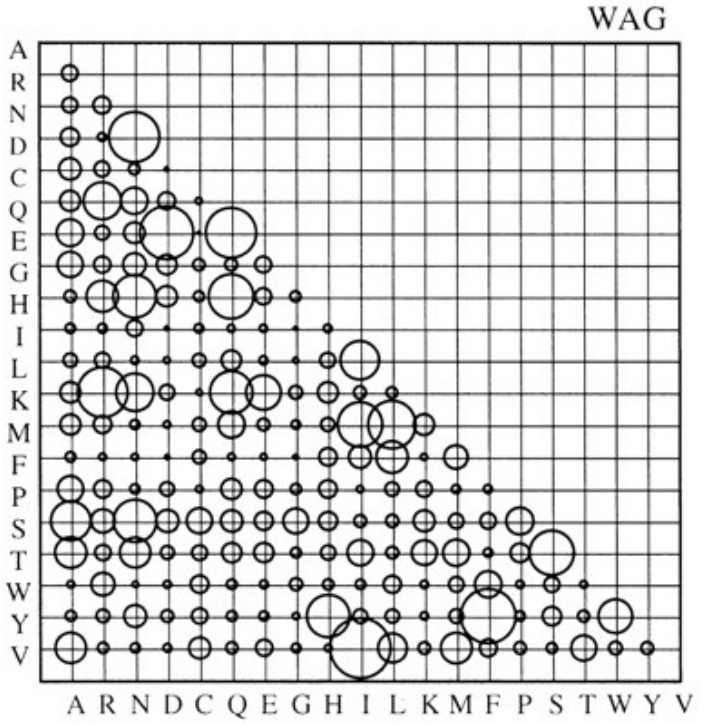
Homogeneous

```
CGTTAGTACACT
CGATAGTTCACT
CGTTAGTTTACC
CATTGGTTTACT
```

Independent across sites

Amino acid substitution matrices

- 20x20 matrix of substitution probabilities
- Too many parameters to estimate
  - GTR model for DNA: 6 parameters
  - GTR model for proteins: 190 parameters
- Estimate substitution probabilities using large data set
  - PAM
  - BLOSUM
  - JTT
  - WAG



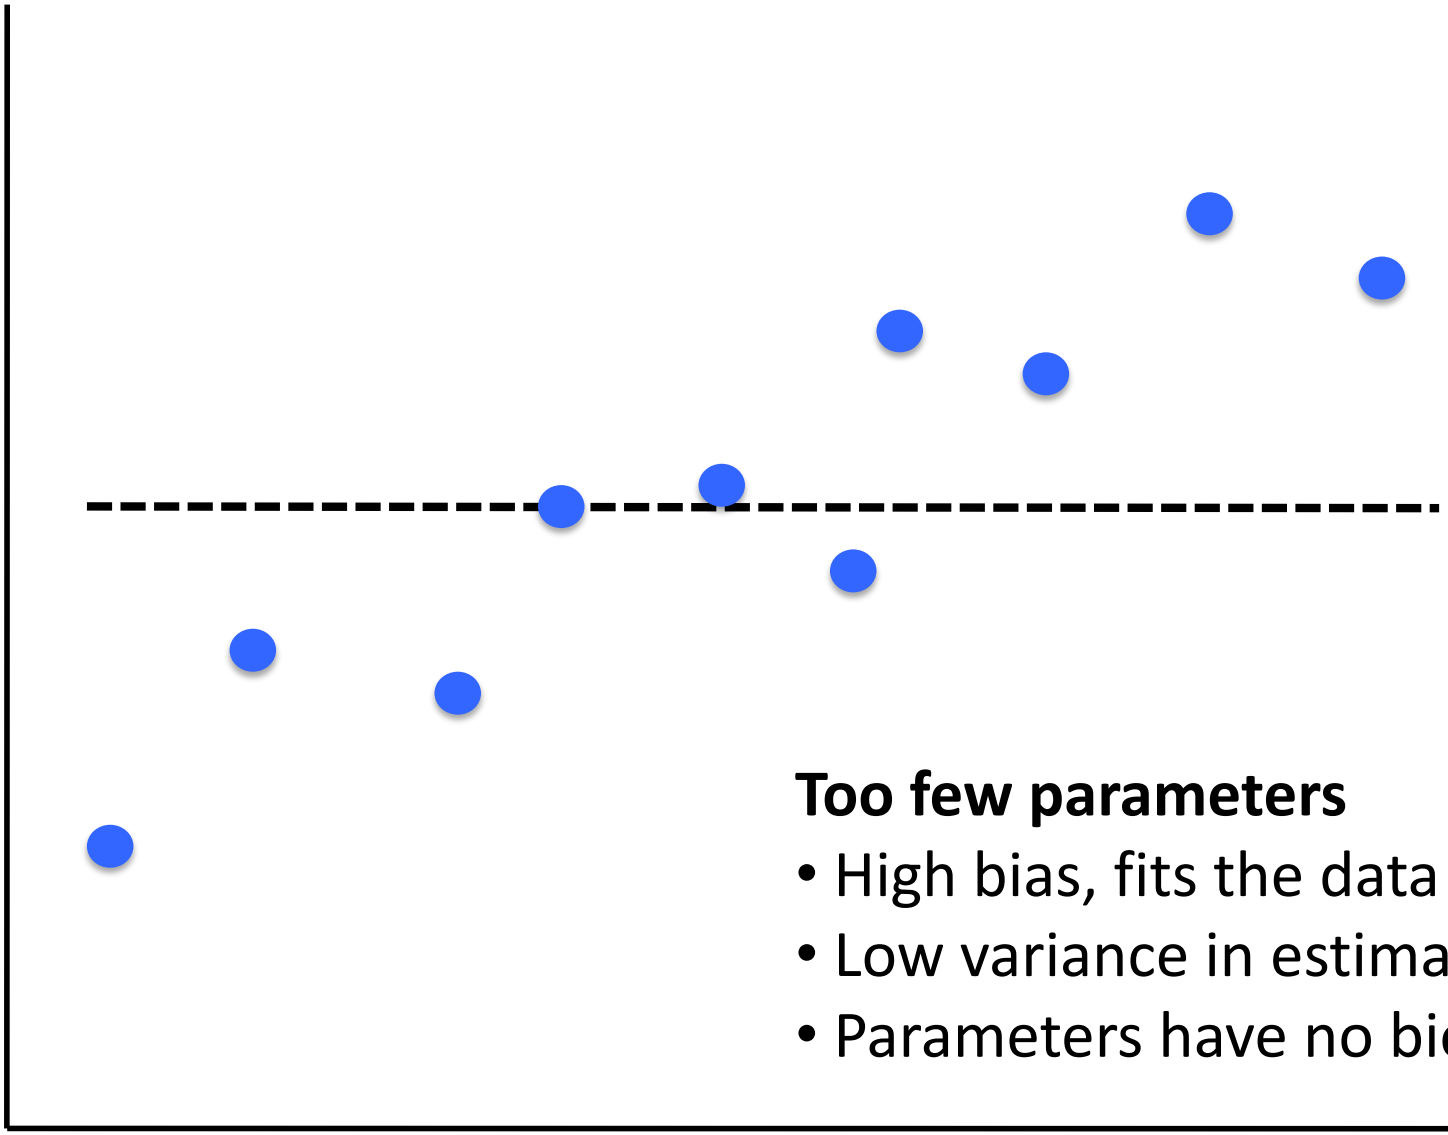
Model Selection

Model selection

1. **Subjective model selection**
   - Pick a model that seems sensible
   - Balance the number of parameters against the amount of data
   - Biological motivation

2. **Objective model selection**
   - Use information theory and let a computer do it for you
   - Statistical motivation

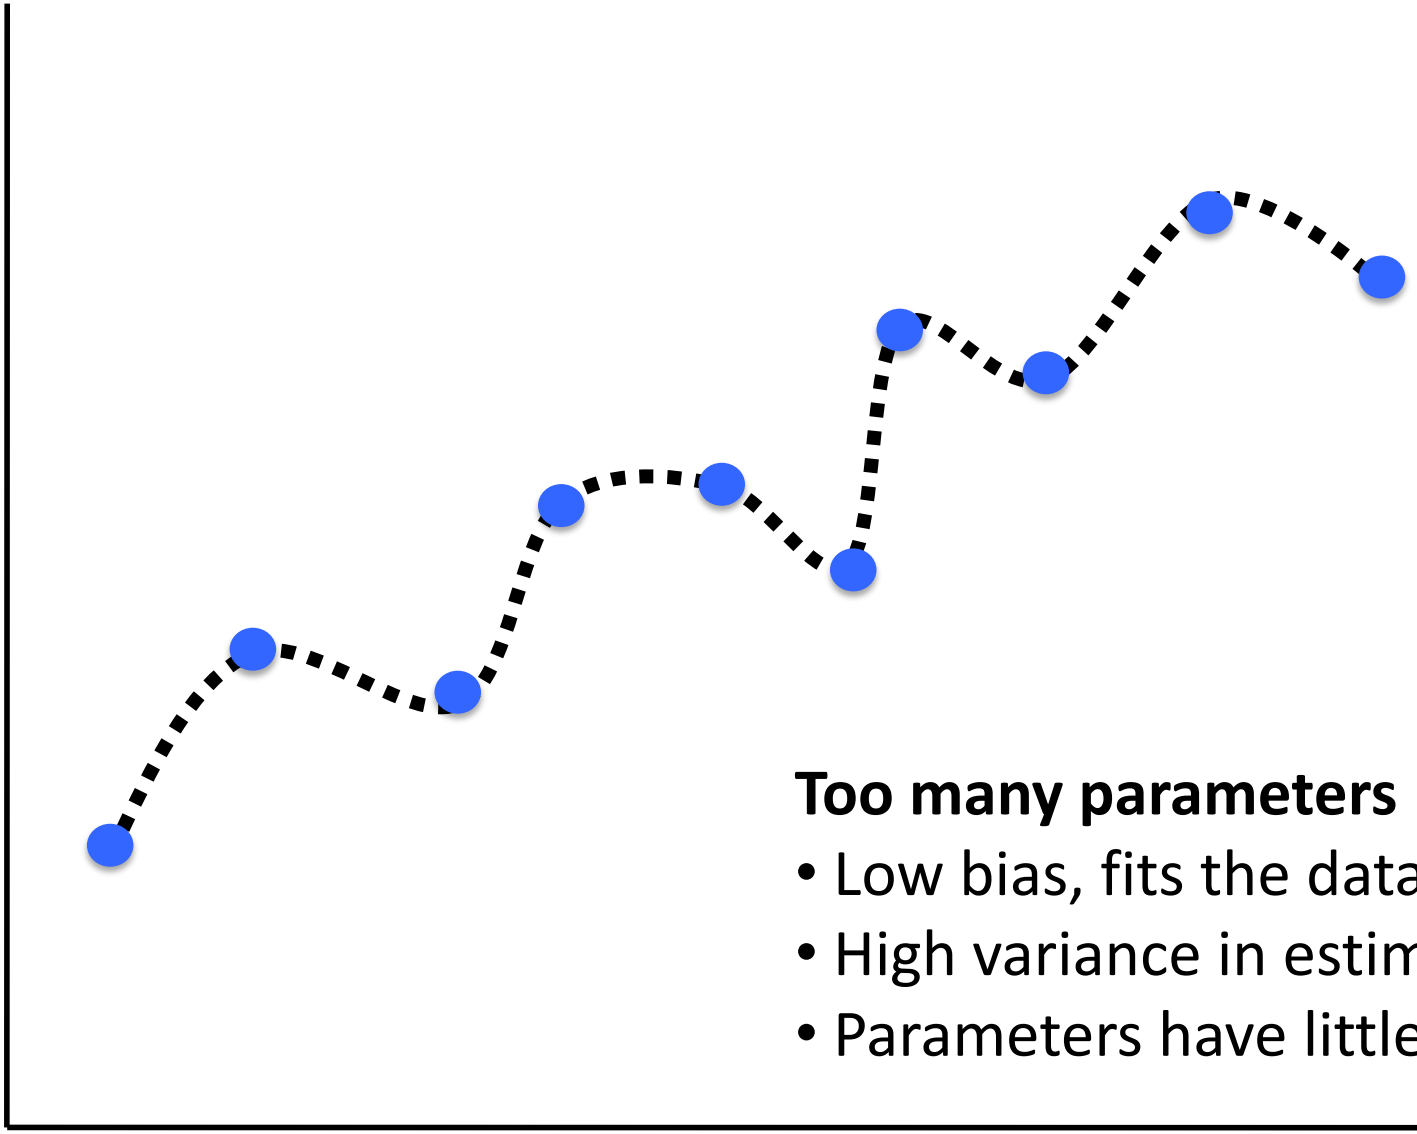
Model selection



Too few parameters

- High bias, fits the data poorly
- Low variance in estimate
- Parameters have no biological meaning

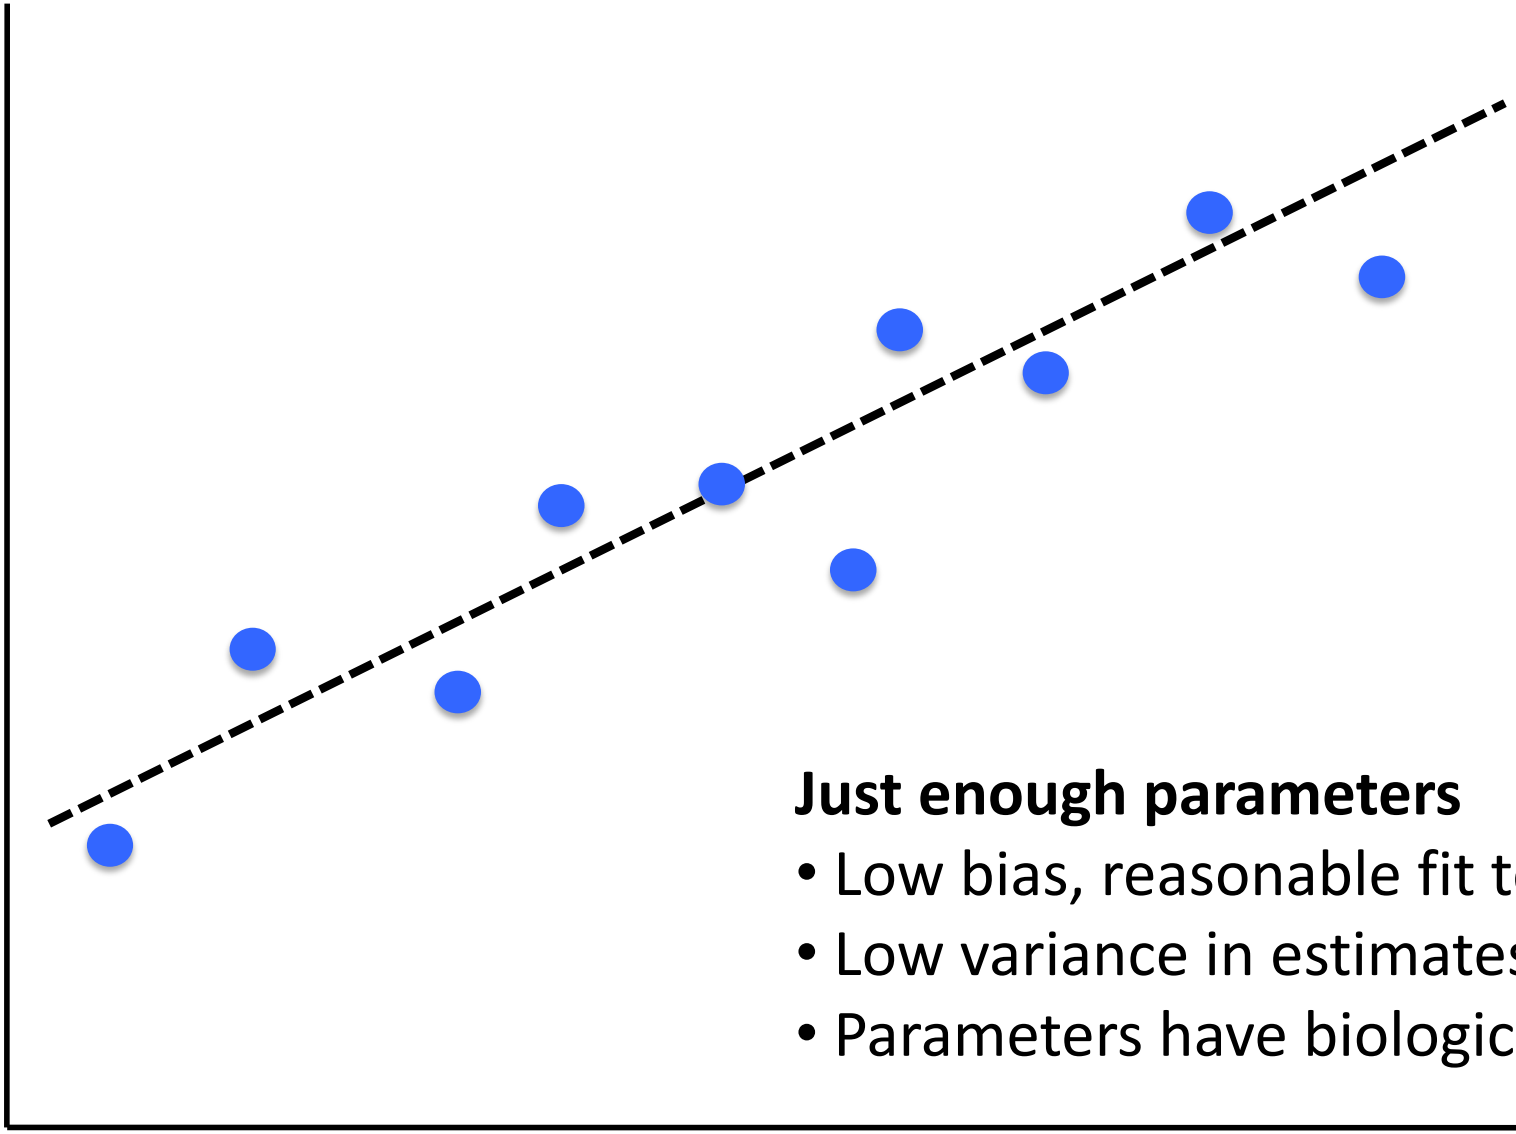
Model selection



Too many parameters

- Low bias, fits the data very well
- High variance in estimates
- Parameters have little biological meaning

Model selection



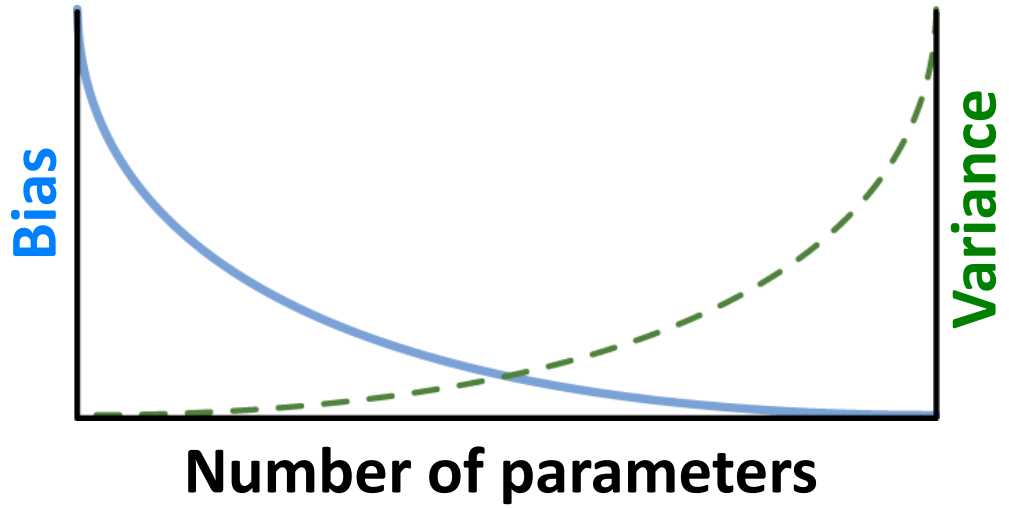
Just enough parameters

- Low bias, reasonable fit to data
- Low variance in estimates
- Parameters have biological meaning

Model selection

- Adding more parameters *always* improves the fit of the model to the observed data
- But more parameters leads to greater variance in the estimates of those parameters

Is the improvement in likelihood worth the cost of adding a parameter?

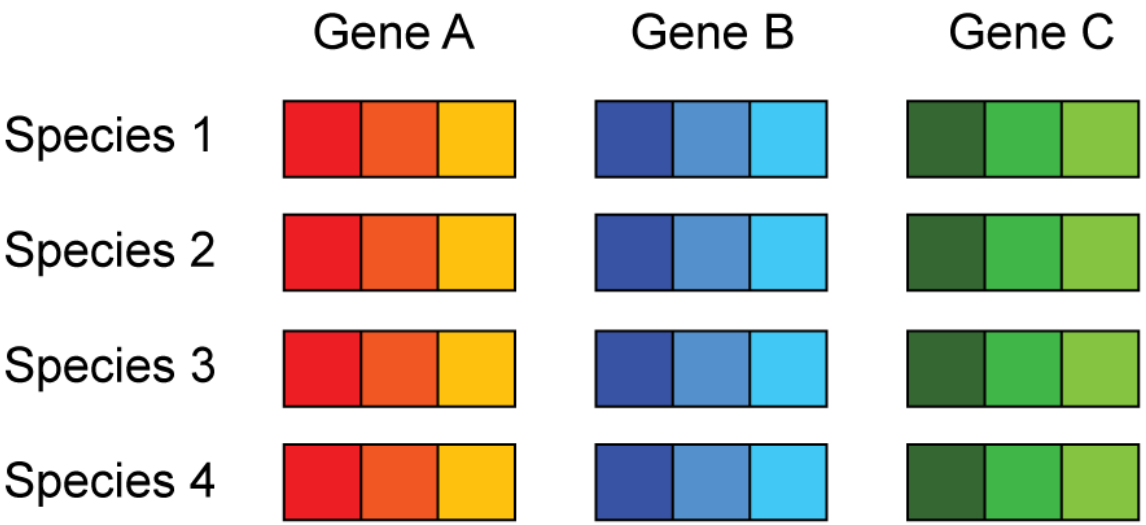


Model selection

- **Likelihood-ratio test (LRT)**
  Used to compare nested models
- **Akaike information criterion (AIC)**
  AIC = -2ln(likelihood) + 2*k*
- **Bayesian information criterion (BIC)**
  BIC = -2ln(likelihood) + *k*ln(*n*)

Data partitioning

- Separate substitution model for each gene and codon position?



- **Biological**
  - Genome
  - Genes
  - Codon positions
  - RNA stems *vs* loops
  - Hydrophobic *vs* hydrophilic
- **Statistical**

PartitionFinder

- Too many possible partitioning schemes
  - 15 schemes for 4 genes
  - 52 schemes for 5 genes
  - 203 schemes for 6 genes

PartitionFinder: Combined Selection of Partitioning Schemes and Substitution Models for Phylogenetic Analyses

Robert Lanfear,[*,1] Brett Calcott,[1,2] Simon Y. W. Ho,[3] and Stephane Guindon[4]

2012 – *Molecular Biology and Evolution*, 29: 1695–1701.

Substitution models in practice

- Phylogenetic estimates are usually robust to choice of model
- **GTR+G** is fine for most data sets
- Sensible data partitioning (*e.g.*, by codon position)
